WARNING

Operations

add:

- put at the bottom
- while order is broken, rise.

get_max:

- swap root with last item
- remove last item
- while order is broken, sink.

sink
(swapping with
largest child)

A concrete implementation

```
# Make the item at index k sink to the correct position.  
def sink(self, k):
```

A concrete implementation

```
# Make the item at index k sink to the correct position.  
def sink(self, k):  
    while 2*k <= self.count:
```

k has at least one child

A concrete implementation

Make the item at index k sink to the correct position.

```
def sink(self, k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:
```

item is larger than largest child

A concrete implementation

Make the item at index k sink to the correct position.

```
def sink(self,k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:  
            break
```

leave the loop

A concrete implementation

Make the item at index k sink to the correct position.

```
def sink(self,k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:  
            break  
        self.swap(child,k)  
        k = child
```

update k

A concrete implementation

```
def largest_child(self, k):
```

```
# Make the item at index k sink to the correct position.
```

```
def sink(self, k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:  
            break  
        self.swap(child, k)  
        k = child
```

A concrete implementation

```
def largest_child(self, k):  
    if self.array[2*k] > self.array[2*k+1]:  
        return 2*k  
    else:  
        return 2*k+1
```

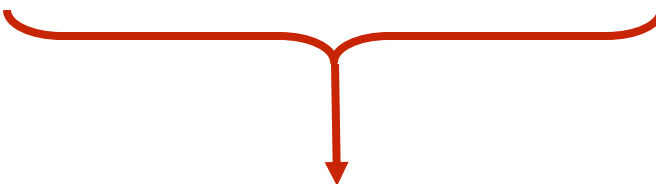

There is a subtle
error here...

Make the item at index k sink to the correct position.

```
def sink(self, k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:  
            break  
        self.swap(child, k)  
        k = child
```

A concrete implementation

```
def largest_child(self, k):  
    if self.array[2*k] > self.array[2*k+1]:  
        return 2*k  
    else:  
        return 2*k+1
```

what if k only has one child

Make the item at index k sink to the correct position.

```
def sink(self, k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:  
            break  
        self.swap(child, k)  
        k = child
```

left child in last position means
k has only one child

```
def largest_child(self, k):  
    # Check for only one child.  
    if 2*k == self.count or self.array[2*k] > self.array[2*k+1]:  
        return 2*k  
    else:  
        return 2*k+1
```

Make the item at index k sink to the correct position.

```
def sink(self, k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:  
            break  
        self.swap(child, k)  
        k = child
```

On subtle errors

- Errors like that are very easy to make, and hard to spot.
- Your armoury against them includes:
 - ☐ Thorough testing
 - ☐ Code review
 - ☐ Proofs of correctness

k=1

self.count = 10

self.array

	15	20	12	14	15	5	7	3	8	10
0	1	2	3	4	5	6	7	8	9	10

```

def largest_child(self, k):
    # Check for only one child.
    if 2*k == self.count or self.array[2*k] > self.array[2*k+1]:
        return 2*k
    else:
        return 2*k+1

```

Make the item at index k sink to the correct position.

```

def sink(self, k):
    while 2*k <= self.count:
        child = self.largest_child(k)
        if self.array[k] >= self.array[child]:
            break
        self.swap(child, k)
        k = child

```

    while 2*k <= self.count:
        child = self.largest_child(k)
        if self.array[k] >= self.array[child]:
            break
        self.swap(child, k)
        k = child
  
```

best case: $O(1)$

worst case: $O(\log N)$

(may need to consider
comparison operations)

Complexity of get_max

- Loop in **sink** can iterate at most depth times $\approx \log(N)$
(after depth iterations, the new item is at the root)
- **Best case: $O(1)$** *OCompare when the item is larger or equal than largest children.
- **Worst case: $O(\log N)$** *OCompare when the item sinks all the way to the bottom.

Homework: (key, value)

```
def largest_child(self, k):  
    # Check for only one child.  
    if 2*k == self.count or self.array[2*k] > self.array[2*k+1]:  
        return 2*k  
    else:  
        return 2*k+1
```

Make the item at index k sink to the correct position.

```
def sink(self, k):  
    while 2*k <= self.count:  
        child = self.largest_child(k)  
        if self.array[k] >= self.array[child]:  
            break  
        self.swap(child, k)  
        k = child
```

Just the key...

Heap sort

Heap sort

- For each element in the array:
 - ☞ Add it to the Heap: $O(\log(N))$**N times**
- While heap contains elements:
 - ☞ Get max item: $O(\log(N))$**N times**

$$\begin{aligned}\log n! &= \log(1 \cdot 2 \cdot 3 \cdot \dots \cdot n) \\ &= \log 1 + \log 2 + \log 3 + \dots + \log n \\ &\leq \log n + \log n + \log n + \dots + \log n \\ &= n \log n\end{aligned}$$

Heap sort

Construction can also be done in linear time

- For each element in the array:
 - ☞ Add it to the Heap: $O(\log(N))$**N times**
- While heap contains elements:
 - ☞ Get max item: $O(\log(N))$**N times**

worst case: $O(N \log N)$

Summary

- A simple Heap implementation
 - rise
 - sink
 - largest_child
- Heap Sort
